TITLE: Short-period internal wave measurements by means of echo sounding

SOURCE: Acta geophysica polonica, v. 14, no. 2, 1966, 121-125

TOPIC TAGS: oceanographic ship, sound waves, oceanographic research, echo sounding, underwater sound wave reflection

ABSTRACT: During oceanographic research in the area of Gdansk Bay (Glebia Gdanska) on the R/V from 29—31 May 1964, systematic echo-sounding observations of layers reflecting sound waves were made. Two distinct echograms were found in the day-night cycle. The nocturnal echogram showed the reflecting layers, i. e., one at the water surface and the other at the bottom. The diurnal echogram recorded one distinct layer at a depth of about 80 m. The depth of this layer changes periodically. At the 80-m depth the computed variation period is ~ 2 min, while measurements give a period of 1.5 min. This means that changes recorded by the echo

TITLE: Vertical heat exchange in the waters of the Baltic Sea during 1950--1962

SOURCE: Przegląd geofizyczny, no. 3, 1966, 183-192

TOPIC TAGS: temperature distribution, sea water, temperature measurement,
turbulent heating / *Baltic Sea*

ABSTRACT: Vertical temperature distribution in the waters of the Baltic Sea is investigated using as the reference the international survey point, the Gdansk Depth, P_1 . (ca. 110m). Of the two basic factors affecting the vertical temperature distribution at a given point (turbulent heat exchange and heat advection from the Northern Sea) the first is studied in detail due to its greater importance. The effect of the interface, across which a significant density shift occurs, upon the vertical temperature distribution is thoroughly covered. The interface divides the upper layer, affected by solar heat, from the lower layer, which is under the influence of heat advection from the Northern Sea. It was established that the Fjeldstad method is satisfactory in the determination of the molecular as well as the turbulent heat transfer. The calculated magnitude of the coefficient K_z , which varies

Card 1/2

with the depth, indicates whether the process is turbulent. The annual variations in the temperature of the studied area are illustrated. Orig. art. has: 11 formulas, 2 tables, and 5 figures.

Group.

Abs Jour: Ref Zhur-Biol., No 16, 1958, 72122.

Abstract: biochemical properties strains of type alpha were divided into 7 groups, strains of type beta - into 4. On the basis of the division the relationship was stated to saccharose, rhamnose, dulcitol, maltose and sorbitol. Part of the alpha-strains were inactivated during isolation, but after a series of passages became active. A majority of the beta-strains possessed the antigenic formula 0111:B4:H₂ and corresponding biochemical properties. A significant part of the strains differed from them in relation to saccharose, dulcitol and sorbitol. A great majority of the strains of the beta type possessed the antigenic formula 055:B5:H₆, and

TITLE: Design and technology of type DCB-60 and DCB-40 halogen counters

SOURCE: Przegląd elektroniki, no. 5-6, 1963, 290-292

TOPIC TAGS: halogen counters, Gamma rays, radiation, neon, bromine

ABSTRACT: Descriptions are given of the DCB-60 and DCB-40 halogen counters for measuring Gamma-ray intensity in the 0.5-40 and 2-200 hr ranges, developed at the Przemysłowy Instytut Elektroniki (Industrial Institute of Electronics [Poland]). The concentric position of the anode inside the cathode cylinder is an essential feature of the counter design, since anode centering has a considerable effect on the maximum current of the counter. This problem was solved by using steatite insulators to hold the anode in place. The cathode of the counter was made of CrFe covered with Cr_2O_3 . The counters are filled with a mixture of neon and bromine. The DCB-60 counter operates in the -20 to +55°C temperature range and the DCB-40, in the -40 to +50°C range. AUTHOR: Kowalska, Krystyna

TITLE: Multizone reactor calculations

PERIODICAL: Nukleonika, v. 6, no. 3, 1961, 157-168

TEXT: In this paper, the author describes the use of the two-group diffusion equations together with an iteration procedure proposed by A.D. Galanin (Ref. 2: Teoriya yadernykh reaktorov na teplovykh neytronakh (Theory of Thermal Nuclear Reactors) Moscow, 1959, Atomizdat) for determining critical size and neutron flux distribution in cylindrical multizone reactors. The basic two-group equations, together with the boundary conditions of flux and radial current continuity are first introduced. The normal modification of the equations to take account of resonance and epithermal neutron capture in the case of uranium-water lattices is also presented as designated by J. Arkuszewski (Ref. 4: Równania "dwu

D209/D303

i pólgrupowe" i ich zastosowanie do układów uranowo-wodnych (Two-and-a-half group" Equations and their Application to Uranium-Water Systems), Nukleonika 3, 166, 1958) and referred to as the two-and-a-half group equations. After stating that the differential equations may be transformed into difference equations by replacing the differential operators by difference quotients, the author proceeds to derive the difference equations from elementary considerations of neutron conservation. The reactor is taken to be multi-zonal in the radial direction only, and a buckling term is introduced to account for axial variations. Each zone is divided into a set of concentric annular regions of width Δs (not necessarily constant) and the fast and thermal neutron balance equations for the s^{th} annulus are derived. In solving the equations, a trial value of thermal neutron flux is used, and the ratio of thermal fluxes obtained in successive iterations $\frac{N^{i-1}}{N^i} = \frac{1}{k_{\text{eff}}}$, the inverse of the

Multizone reactor calculations

POL/046/61/006/003/001/005
D209/D303

effective multiplication constant, which will be unity when the reactor is just critical. The solution of the equation consists, therefore, in determining the width of the neutron multiplying zone, the width of the other zones being fixed, for which

$\frac{N^{i-1}}{N^i} = 1$. Taking Δ_s constant throughout a zone, gave inaccurate flux distributions, particularly at the zone boundaries. Thus, values of Δ_s were distributed throughout a zone by a parabolic relation, ensuring small values near boundaries and larger values at the center. The total number of points was specified for the zones with fixed boundaries, but was taken proportional to the zone width for the neutron multiplying zone. The first calculations used a suggestion by Soviet colleagues /Abstractor's note: No names given/ that there should be 13 lattice points in the core and 5 in the reflector. However, when the variable Δ_s system was introduced

Card 3/6

Multizone reactor calculations

POL/046/61/006/003/001/005
D209/D303

an average of 30 points was used. The calculations may be extended to more than two groups and more than three zones, depending on the available computational facilities, "URAL 2" being mentioned in this context. A description of the computing procedure follows. It starts with a trial thermal flux value of 1 in all regions, and after several recursions the ratio

$$\frac{N^{i-1}}{N^i}$$

converges to some limit. If this differs from 1 by less than 10^{-4} , the system is critical. If this situation is not reached, the computer adjusts the values of Δ_s in the multiplying zone and repeats the calculation. On completion of the computation, the computer records all nuclear parameters used, the number of spatial points in each zone, the final values of $\frac{N^{i-1}}{N^i}$, Δ_s , and the coefficients in

Card 4/6

Multizone reactor calculations

POL/046/61/006/003/001/005
D209/D303

the difference equations, together with the neutron fluxes at all spatial points. So far, calculations have only been made for Δ_s constant in a zone, and a total of 18 spatial points. Assemblies considered have been: a) Graphite reflected, 20 % enriched water reactor with central water neutron trap; b) (a) with an indium sulphate filled central irradiation loop; c) 90 % enriched, graphite-moderated and -reflected, water-cooled zero power assembly with central power loop mock-up; d) High flux reactor of type (c); e) Central uranium-water lattice as in (a) surrounded by a natural uranium-graphite lattice, water-cooled and graphite-reflected. Calculations were performed by the medium-size computer XYZ built in the Computer Research Center of the Polish Academy of Sciences, which took about half an hour for each calculation. Results of the first two calculations were checked by the desk computer, and the accuracy was checked by using the adjoint equations for neutron importance. These indicate an accuracy of about 5 %, although the accuracy of computation is 1 in 10^5 . Programs are in preparation

Title : The Biological Activity of Raw Rhiz. Valerianae and Its
Oil Content in the Second Year of the Plant's Life.

Orig Pub : Farmac. polska, 1956, 12, No 8, 197-202

Abstract : During the year the oil content fluctuated from 0.5 to
1.5%. The biological activity, determined by Kaminskiy's
method on tench fry, proved to be highest during the
period of intensive growth of the plants in May, and also
during the period of blossoming in the field. The oil
content of the root increases with lower temperature.
Parallelism between the biological activity of the ex-
tract and the oil content in the root was observed. --
Z.I. Zhurbitskiy
